**Preauthorization is required.**

The following protocol contains medical necessity criteria that apply for this service. The criteria are also applicable to services provided in the local Medicare Advantage operating area for those members, unless separate Medicare Advantage criteria are indicated. If the criteria are not met, reimbursement will be denied and the patient cannot be billed. Please note that payment for covered services is subject to eligibility and the limitations noted in the patient’s contract at the time the services are rendered.

Individuals: • With esophageal disorders | Interventions of interest are: • Wireless capsule endoscopy | Comparators of interest are: • Endoscopy | Relevant outcomes include: • Test accuracy • Test validity • Other test performance measures

Individuals: • Who are screened for colon cancer | Interventions of interest are: • Wireless capsule endoscopy | Comparators of interest are: • Optical colonoscopy | Relevant outcomes include: • Test accuracy • Test validity • Other test performance measures

Individuals: • With hereditary gastrointestinal polyposis syndromes | Interventions of interest are: • Wireless capsule endoscopy | Comparators of interest are: • Ilieocolonoscopy • Small bowel follow-through • Computed tomography enterography • Magnetic resonance enterography | Relevant outcomes include: • Test accuracy • Test validity • Other test performance measures

Individuals: • With portal hypertensive enteropathy | Interventions of interest are: • Wireless capsule endoscopy | Comparators of interest are: • Endoscopy | Relevant outcomes include: • Test accuracy • Test validity • Other test performance measures

Individuals: • With unexplained chronic abdominal pain | Interventions of interest are: • Wireless capsule endoscopy | Comparators of interest are: • Standard workup for abdominal pain without capsule endoscopy | Relevant outcomes include: • Test accuracy • Test validity • Other test performance measures

Individuals: • Who are scheduled to undergo capsule endoscopy for known or suspected small bowel stricture | Interventions of interest are: • Patency capsule | Comparators of interest are: • Capsule endoscopy without patency capsule • Alternative workup without capsule endoscopy | Relevant outcomes include: • Test accuracy • Test validity • Other test performance measures

**Description**

The wireless capsule endoscopy uses a device to visualize portions of the bowel that are not accessible via upper or lower endoscopy, primarily the small bowel. Patients swallow a capsule that records images of the intestinal mucosa as it passes through the gastrointestinal (GI) tract. The capsule is collected after being excreted and images interpreted.

**Summary of Evidence**

For individuals who have suspected small bowel bleeding (previously referred to as obscure gastrointestinal [GI]...
bleeding) who receive wireless capsule endoscopy, the evidence includes numerous case series evaluating patients with a nondiagnostic standard workup. Relevant outcomes are test accuracy, test validity, and other test performance measures. The evidence has demonstrated that capsule endoscopy can identify a bleeding source in a substantial number of patients who cannot be diagnosed by other methods, with a low incidence of adverse events. Because there are few other options for diagnosing obscure small bowel bleeding in patients with negative upper and lower endoscopy, this technique will likely improve health outcomes by directing specific treatment when a bleeding source is identified. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals who have acute upper GI tract bleeding who receive wireless capsule endoscopy, the evidence includes one RCT and several cohort studies. Relevant outcomes are test accuracy, test validity, and other test performance measures. The use of capsule endoscopy in the emergency department setting for suspected upper GI bleeding is based on efficiency (avoiding hospitalization, avoiding immediate endoscopy). Further controlled studies are needed to further assess the impact of capsule endoscopy on health outcomes compared with standard management. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals who suspected small bowel Crohn disease or individuals with an established diagnosis of Crohn disease who receive wireless capsule endoscopy, the evidence includes case series. Relevant outcomes are test accuracy, test validity, and other test performance measures. Although the test performance characteristics and diagnostic yields of the capsule for these indications are uncertain, the diagnostic yields are as good as or better than other diagnostic options, and these data are likely to improve health outcomes by identifying some cases of Crohn disease and directing specific treatment. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals who have ulcerative colitis, suspected celiac disease, esophageal disorders, hereditary polyposis syndromes, colon cancer screening, portal hypertensive enteropathy, or unexplained chronic abdominal pain, the evidence includes case series and diagnostic accuracy studies. Relevant outcomes are test accuracy, test validity, and other test performance measures. For some of these conditions (e.g., esophageal conditions, colon cancer screening), other available modalities are superior to capsule endoscopy. The diagnostic characteristics of capsule endoscopy are not good enough to substitute for other modalities or to triage patients to other modalities. For other conditions (e.g., determining the extent of Crohn disease), direct evidence of improved outcomes or a strong indirect chain of evidence to improved outcomes is lacking. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals who are scheduled to undergo capsule endoscopy for known or suspected small bowel stricture who receive a patency capsule, the evidence includes case series. Relevant outcomes are test validity and other test performance measures. The available studies have reported that capsule endoscopy following a successful patency capsule test results in high rates of success with low rates of adverse events. The capsule is also associated with adverse events. Because of the lack of comparative data to other diagnostic strategies, it is not possible to determine whether use of the patency capsule improves net health outcomes. The evidence is insufficient to determine the effects of the technology on health outcomes.

Policy

Wireless capsule endoscopy of the small bowel may be considered medically necessary for the following indications:

- Initial diagnosis in patients with suspected Crohn disease without evidence of disease on conventional diagnostic tests such as small-bowel follow-through and upper and lower endoscopy.
• In patients with an established diagnosis of Crohn disease when there are unexpected change(s) in the course of disease or response to treatment suggesting the initial diagnosis may be incorrect and re-examination may be indicated.

• Suspected small bowel bleeding, as evidenced by prior inconclusive upper and lower gastrointestinal (GI) endoscopic studies performed during the current episode of illness.

• For surveillance of the small bowel in patients with hereditary GI polyposis syndromes including familial adenomatous polyposis and Peutz-Jeghers syndrome.

Other indications for wireless capsule endoscopy are considered investigational, including but not limited to:

• Evaluation of the extent of involvement of known Crohn disease or ulcerative colitis.

• Evaluation of the esophagus in patients with gastroesophageal reflux or other esophageal pathologies.

• Evaluation of other GI diseases and conditions not presenting with GI bleeding including but not limited to celiac sprue, irritable bowel syndrome, Lynch syndrome, portal hypertensive enteropathy, small bowel neoplasms and unexplained chronic abdominal pain.

• Evaluation of the colon including but not limited to detection of colonic polyps or colon cancer.

• Initial evaluation of patients with acute upper GI bleeding.

The patency capsule is considered investigational including use to evaluate patency of the GI tract before wireless capsule endoscopy.

Policy Guidelines

Obscure GI bleeding is defined as “recurrent or persistent iron-deficiency anemia, positive fecal occult blood test, or visible bleeding with no bleeding source found at original endoscopy.” (Van Gossum 2001)

Background

Wireless capsule endoscopy is performed using the PillCam Given Diagnostic Imaging System (previously called M2A), which is a disposable imaging capsule manufactured by Given Imaging. The capsule measures 11 by 30 mm and contains video imaging, self-illumination, and image transmission modules, as well as a battery supply that lasts up to eight hours. The indwelling camera takes images at a rate of two frames per second as peristalsis carries the capsule through the GI tract. The average transit time from ingestion to evacuation is 24 hours. The device uses wireless radio transmission to send the images to a receiving recorder device that the patient wears around the waist. This receiving device also contains localizing antennae sensors that can roughly gauge where the image was taken over the abdomen. Images are then downloaded onto a workstation for viewing and processing.

In the small bowel, the capsule camera has been most frequently proposed as a technique to identify the source of obscure intestinal bleeding, although recently there has been interest in exploring its use in patients with inflammatory bowel disease. Alternative diagnostic techniques include barium studies or small intestinal endoscopy. In the esophagus, the capsule camera has been proposed as a screening technique for Barrett esophagus associated with gastroesophageal reflux disease. Evaluation of the esophagus requires limited transit time, and it is estimated that the test takes 20 minutes to perform. Alternative techniques include upper endoscopy.
Regulatory Status

In August 2001, the PillCam™ Given® Diagnostic Imaging System (Given Imaging) was cleared for marketing by the U.S. Food and Drug Administration (FDA) through the 510(k) process. FDA clearance provides for the capsule’s use “along with – not as a replacement for – other endoscopic and radiologic evaluations of the small bowel.” FDA clarified that the “capsule was not studied in the large intestine.” In July 2003, after a supplemental 510(k) premarket notification, the labeled indications were modified by removing the “adjunctive” use qualification: “the Given® Diagnostic System is intended for visualization of the small bowel mucosa. It may be used as a tool in the detection of abnormalities of the small bowel.”

In November 2004, the device received FDA clearance for the following labeled indication: “the Given® Diagnostic System with the PillCam™ ESO Capsule is intended for the visualization of esophageal mucosa.” A new model (PillCam™ ESO2 Capsule) was cleared by FDA in June 2007. In September 2007, the Olympus Capsule Endoscope System was cleared for marketing by FDA through the 510(k) process for “visualization of the small intestine mucosa.” More recent versions of both systems also incorporate a blood indicator feature to assist with rapid screening of intestinal lesions with bleeding potential.

In 2006, the Given AGILE™ patency system was cleared by FDA through the 510(k) process. This system is an accessory to the PillCam™ video capsule and, according to FDA, is intended to verify adequate patency of the GI tract before administration of the PillCam™ into patients with known or suspected strictures. This capsule is of similar size to the endoscopy capsule but made of lactose and barium and dissolves within 30 to 100 hours of entering the GI tract. It carries a tracer material that can be detected by a scanning device. Excretion of the intact capsule without symptoms (abdominal pain or obstruction) is reported to predict the uncomplicated passage of the wireless capsule.

In 2014, PillCam™ COLON was cleared for marketing by FDA through a de novo 510(k) classification. The new classification applies to devices with low-to-moderate risk that have no predicate on the market. PillCam™ COLON is intended to visualize the colon in patients who have had an incomplete colonoscopy due to a technical impossibility and not incomplete evacuation. In 2016, the PillCam™ COLON 2 Capsule Endoscopy System was cleared by FDA through the 510(k) process for the detection of colon polyps in patients after an incomplete colonoscopy with adequate preparation, and a complete evaluation of the colon was not technically possible, and for detection of colon polyps in patients with evidence of GI bleeding of lower GI origin in patients with major risks for colonoscopy or moderate sedation, but who could tolerate a colonoscopy and moderate sedation in the event that a clinically significant colon abnormality was identified on capsule endoscopy.

FDA product code: NEZ.

Services that are the subject of a clinical trial do not meet our Technology Assessment Protocol criteria and are considered investigational. For explanation of experimental and investigational, please refer to the Technology Assessment Protocol.

It is expected that only appropriate and medically necessary services will be rendered. We reserve the right to conduct prepayment and postpayment reviews to assess the medical appropriateness of the above-referenced procedures. Some of this protocol may not pertain to the patients you provide care to, as it may relate to products that are not available in your geographic area.
